DEDICATION

The project is dedicated to AlmightyGod the giver of knowledge and understanding and to my parent **MR. & MRS. ODENIRAN.**

ACKNOWLEDGEMENTS

I acknowledge the love guidance and favour of God almighty for the successful completion of the programme

I also appreciate the professional of my supervisor SURV. R.S AWOLEYE , during the course of writing this project, I shall forever be grateful to you

This acknowledge will not be complete if I did not appreciate the great work and effort of some personnel in great and noble institution; SURV. ISAU ABIMBOLA (H.O.D) Surveying and Geo-informatics

I am also grateful to all my lecture that made my stay in school inevitable and without forgetting those that contributed in several way towards the successful completion of my academic career in this institution and towards the complete of my project work most especially SURV. R.OASONIBARE and SURV A.G AREMU, SURV BELLO FELIX DIRAN, SURV BANJI, SURV WILLIAMS KAZEEM, SURV BABATUNDE KABIR, SURV ABDULSALAM AYUBA

MY unreserved gratitude goes to my lovely mummy and daddy and my brother, sister, and my lovely wife ADEYEMO IFEOLUWA RODAH for their immeasurable support financially, spiritually, love and advice towards the success of this programme may God in his infinite mercy be with you and strengthen you the more in Jesus name (Amen). I love you so much; you are such a wonderful family.

I want to personally appreciate my in-law Olowokanga Omosuyi Olumide for his great support based on finance, advice and my well being. God will rewards you, and continue to bless you.

ABSTRACT

The cadaster is a land information system containing up-to-date records of interest in land. This system will normally have a base expressing the location of the land as one of the important components of a cadaster system is the cadastral map, but existing system consisting of paper maps and convention on land registry are becoming obsolete and ineffective. This project centers on cadastral information system of part of Irewolede Estate, Along New Yidi Road Ilorin, of Ilorin South local government area Ilorin, Kwara state Nigeria, it covers reconnaissance survey,

database design of the area, fieldworks, data processing and analysis, social survey, data presentation. The project content includes the reconnaissance survey which is made up of the office and field reconnaissance, this study describes the design and implementation of a cadastral database with a spatial modeling approach. The objectives are to produce a design of a spatial database that fulfills the requirement for spatial queries for cadastral data. Implementing this design in the study area, and enforce the development of multipurpose cadastral data, data acquisition, physical designs, analysis and implementation of the database system. Attribute data were also obtained by personal enquires and observation (social survey), the graphics drafting was done in AutoCAD and later imported to ArcGIS 10.2 for the data analysis, queries and presentation of final results. Queries were performed and generated to demonstrate the capabilities of the software used and the database created. The outputs were then presented in graphical form. In conclusion the automated land registration provides effective and efficient documentation and reduces the need for paper records duplication.

CHAPTER ONE

INTRODUCTION

1.1 BACKGROUND TO THE PROJECT

Land is an ultimate resource for without it life on earth cannot be sustained. Land has been identified as perhaps the single most natural resource of any nation on which human and economic activities take place. It is at the basis of all societies, it is so basic that it affects the people's way of living, the agricultural system practiced, the food, shelter, clothing etc. has been identified as a function of virtually all forms of production (Rafidif, 1976) and is required for various uses in both urban and rural areas of all societies. In African countries, the tremendous importance of land is not only reflected in its economic value, but also its spiritual significance. The growth and sustainable development of any nation is that nation's access to reliable and sufficient geo-information (ATBU 2011). Surveying, which is also interchangeably called geomatics, has traditionally been defined as the science, art and technology of determining the relative position of points above, on or beneath the earth's surface, or of establishing such points in a more general sense, however surveying can be regarded as that discipline which encompasses all methods for measuring and collecting information about the physical earth and our environment, processing that information and disseminating a variety of resulting products to a wider range of clients. (Charles D. Ghilani and Paul R. Wolf 2012).

Cadastral information system (CIS) as the name implies is the combination of cadastral surveying and geographic information system. So for better knowledge of what cadastral information system (CIS) entails, cadastral surveying and geographic information system (GIS) cannot be over emphasized.

Cadastral surveying answers the questions where is the land located, and what is the extent (size) of its boundaries and surface area? It also indicates the land parcel's separate identity both geographically on a map or record and physically on the ground by means of survey beacons. Cadastre on the other hand answers the questions concerning ownership of the land and the conditions under which it is held. Because of the close connection of cadastral surveying to land, it is directly controlled by law. Thus chapter 194 of the laws of the federation of Nigeria and Lagos of June 1958, deals with this aspect of surveying profession. Cichocinski, (1999).

or cards is not only inefficient but also cumbersome to operate. Parcel-related information cannot be collected and disseminated systematically and regularly, nor can they be managed effectively to support user's needs. In classical method, Land records stand the risk of physical damage from rain, fire or other forms of hazard. Moreover, manual data handling exposes the original records to excessive wear and tear due to rough handling of the paper maps.

1.2 AIM AND OBJECTIVE OF THE PROJECT

1.2.1 AIM OF THE PROJECT

The project was aimed at coming out with a plan showing a comprehensive information of part of Hajj Camp for use most especially for Planning purpose, policy making and implementation of part of Hajj Camp area Ilorin west local government area Ilorin Kwara state, Nigeria.

1.2.2 OBJECTIVES OF THE PROJECT

In executing this project, the following objectives were strictly adhered to.

1. Reconnaissance
2. Database design
3. Data acquisition
4. Data downloading and processing

5. Databasecreation

6. Mapproduction

7. Comprehensivereportwriting

1.3 SCOPE OF THE PROJECT

The scope of this project includes the following;

- a) Reconnaissance: locating controls and fixing point
- b) Data acquisition: office planning, fieldwork (field observation) using digital equipment with total station.
- c) Data downloading and processing: Data downloading and editing from sokkia, computations, design and creation of database and spatial analysis, linking of attributed data with geometric data.
- d) Database creation: Design and construction of database, spatial analysis, and query ArcGIS.
- e) Database Design: view of reality, conceptual design and logical design
- f) Map production: composite maps and soft and hard copies
- g) Technical report: comprehensive report on the topic

1.4 PERSONNEL

The student listed below were the members of this group who participated in the execution of the project

| Matric Number | Name | Remark |

1.5 STUDY AREA

The study area for the project is situated on Part of Irewolede Estate, Ilorin West Local Government Area, Kwara State. The geographic location of the study area lies between latitude 08° 27' 29.94"N to 08° 27' 49.59"N and longitude 04° 32' 56.74"E to 04° 33' 21.36"E. The area covered is approximately found to be 27.2

hectares.

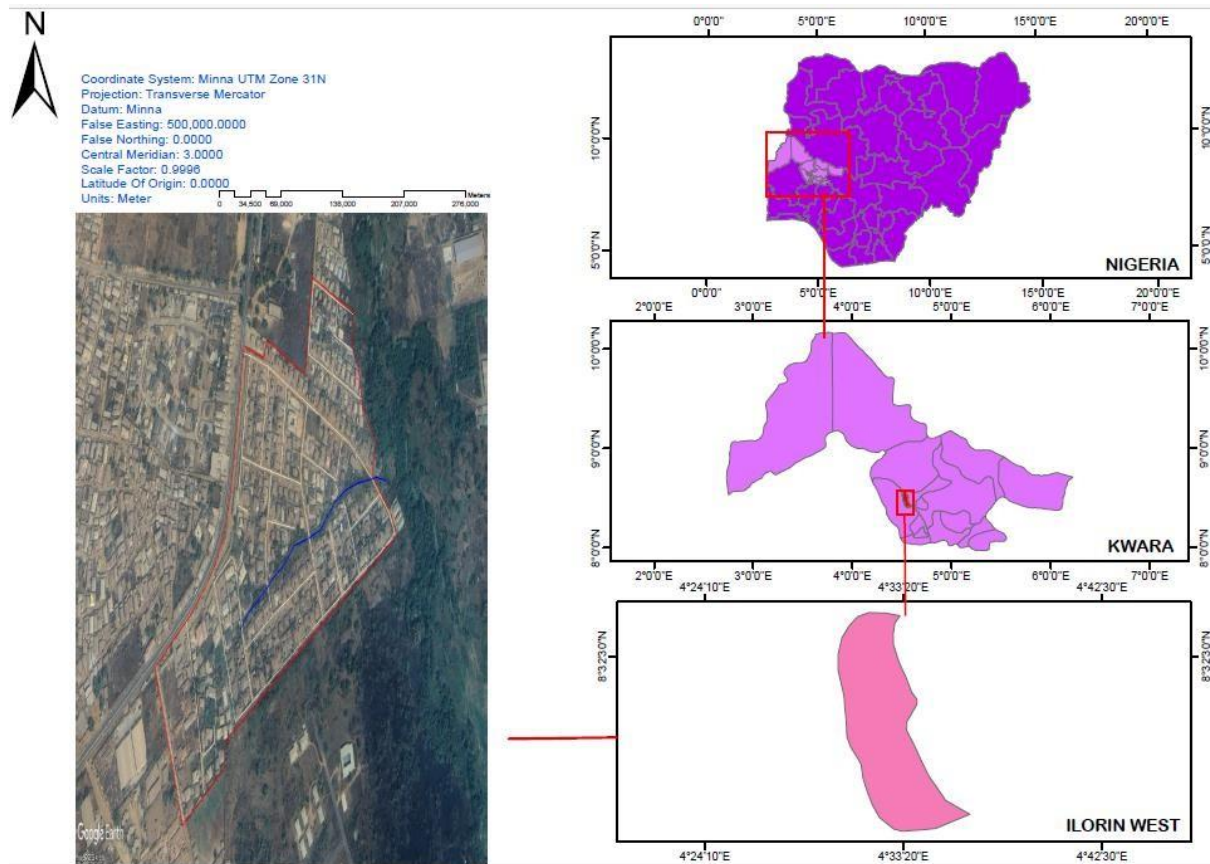

Figure1.1MapoftheStudyArea

CHAPTER TWO

LITERATURE REVIEW

2.0 BASIC CONCEPT AND DEFINITION

Technology evolution is a term that has become a household name today. It cuts across every aspect of human activity and its uniqueness is in the fact that it is dynamic in nature. With every passing day there is a new phase of physical development embarked upon and the bulk of these activities are land-based hence there is a great need for the effective utilization and management of land which is irreplaceable natural resources. Information on land parcels and its attributes (e.g. title, size, shape, and location etc.) and other properties on the land are very vital when planning for any form of physical development hence the production of cadastral maps.

As technology developed further, these cadastral maps which were predominantly in analogue forms could not meet the need of the day as regards planning and development. Sophistication had taken over virtually all men's operations in the area of physical planning and development and the input spatial data format needed in modern day decision making process is now strange compared to what was earlier obtainable. Relevant information could not be accessed at will and there was no flexibility in the form that these maps existed, these limitations lead to series of research and with the advent of Geography information system (GIS) a great relief came. Cadastral information which earlier existed in analogue forms are now represented in digital forms and could be further integrated into an information system which supports certain spatial operation Demers. In this project certain keywords will be encountered. We shall in this chapter attempt to look critically into these keywords for better understanding. They include; land, cadastral, data, information, system, spatial, database, database management system (DBMS),

information system, geographic information system (GIS), and cadastral information system (CIS).

The International Federation of Surveyors (FIG, 1995) defines a cadastre as a parcel based and up-to-date land information system containing a record of interests" inland (e.g. rights, restrictions and responsibilities). It usually includes a description of land parcels linked to other recordsdescribing the natureofthe interest,ownership or controlofthose interests, and oftenthe value of the parcel improvements. It may be established for fiscal purposes (valuation and taxation), legal purposes (conveyance), to assist in the management of land and land-use (planning and administration) and enables sustainable development and environmental improvement The cadastral infrastructure includes a unique identification of the land parcels deriving from the cadastral survey.

Thecadastralidentification isthenseenasthecorecomponent ofany land informationsystem. It is argued that within the next ten years such land information systems will form an integral part off modelofour man made and naturalenvironment. The modelwill build on the core cadastral and topographic data base which will be complete on a country wide basis and kept up-to-date. The focus will be on providing land information to the mass market to support the land market, financialand businesssectors,environment management,landadministration,urbansystemsand community information systems. This definition of cadastre incorporates the component of land registration, which is the recording of right in land, through deeds or titles.

Suchsystems,inprinciple, thusconsistoftwobasicparts:

(i) A cartographic part, consisting of large-scale rmaps, based on surveys including aerial photographs, which indicate the division into parcels of an area, along with appropriate parcel identifier.

(ii) A descriptive part containing registers or files which record legal facts (deeds) or legal consequences and other physically or abstract attribute concerning the parcels depicted on the map

To individual or citizen

(1) The documented evidence of land ownership, which a cadastre provides, supplies security, reduces or eliminates the risk of eviction and thus enhances the incentives to invest in the land or property.

(2) This legal security affects the availability of resources for financial investment. The supply of credit, especially from institutional or formal resources (e.g. banks), depends usually on the borrower's ability to provide cadastre documented evidence of ownership.

(3) Dealing in land become easier, cheaper, faster and safer. Access to land is consequently improved. Conveyance of unregistered land is often expensive, unsafe and takes a long time.

(4) Increased legal security results in a decrease of title and boundary disputes and related litigation, which saves costs for both government and citizen and promotes good relationship between neighbors Aremu (2014).

To the government or society

(1) A cadastral system enables the government to establish an efficient and equitable levying land or property taxes.

(2) For land development through reform, consolidation or readjustment, the data from the cadastral system provide an inventory of the existing land use to be used in determining the desired fixture situation and its implementation and management that transaction meet the amount of land

(3) A mechanism becomes available to the government to assurance requirement of planning, spatial management, the allowed maximum amount of land per owner (land ceiling), maximum sales price or restriction of lands ownership by foreigners.

(4) Useful tools were also created for the execution of a multitude of other government tasks.

The collected basic data of the cadastral map can also serve as a basis for other large scale maps, which will in the long term result in considerable saving of time and cost it not only facilitate transaction but it also a critical efficient land administration and expedites land market factor in the economic development of a people and country Aremu (2014). Improvements in the study of Cadastral Information System have been witnessed over time. In some countries some projects have been undertaken to extend the conventional system to cover new issues such as:

- i. Automation of administrative tasks.
- ii. Development of applications for managing the cadastral register
- iii. Development of analytical tools for setting up digital cadastral maps and plans.
- iv. Automation of land management for consolidation.
- v. Implementation of land information system

Land" according to Webster's 1913 Dictionary referred to as the solid part of the earth surface opposed to water as constituting a part of such surface, especially to ocean and seas. There is array of natural resources available to humans but land is the basic natural resources of a nation on which any human and economic activities take place. It is the means of life without which his continued existence and progress depends. Land is often referred to as real property which, in every basic terms means property which is fixed and immovable -as distinct from personal property which, again in basic terms, means property (as in goods and chattels) which is not fixed and can be moved. The general principles of ownership at common law have long been

established in the courts of equity although the concept of extent of ownership has changed significantly in interpretation from the nineteenth to the twenty first century. In addition, statutory laws continue to place increasing restrictions on the rights and benefits which would otherwise accrue with land ownership Donnelly (1985).

According to Adeniran (1999), a system is a collection of a component part, or a set of interrelated elements linked up with one another towards achieving a define goal. A system could be a network of components that functions upon the intervention of an operator (human) having peculiar skills or techniques which work together in a given environment for the sole aim of attaining a particular goal.

For the purpose of this project, a system is a set of computer components closely linked together and controlled by qualified personnel to perform a predefined task or set of tasks that are aimed at meeting a particular need, these tasks follow a laid down routine or procedure. This term is used to describe any object located in space or a phenomenon that is occurring within a region of space on the earth. This implies that the earth forms the basis for all spatial objects, phenomenon or activities. All entities encountered in the course of this project are regarded as spatial because they are all referenced to the earth.

A database is a collection of persistent data that is used by the application systems of a given enterprise. By persistent we mean, intuitively that is database data differs in kind from other more ephemeral data, such as input data, output data, control segments, work queues, software control blocks etc. Enterprise refers to a single convenient generic term for any reasonably self-contained commercial, scientific, technical or other organization. This particular project involved the use of data in large volumes and as such these data cannot be conveniently handled unless stored in a database so that they can be easily accessed at will.

A database management system (DBMS) is a program product for keeping computerized records about an enterprise. It is a computerized system whose overall purpose is to store information and to allow users to retrieve and update that information on demand. The information in question can be anything that is of significance to the individual or organization concerned; in other words, that is needed to assist in the general process of running the business of that individual or organization. Abraham, Korth and Sudarshan (2000). For land resource to be effectively and judiciously managed, all data and information pertaining to it must be in a form that it can be easily stored in a database and such data/information set must be flexible. Since the essence of creating this Cadastral Information System (CIS) is to aid physical planning and development and also serve as a Decision Support System (DSS) it is a matter of necessity that an effective database management system (DBMS) be developed to achieve this aim.

An information system is a collection of people, resources, and procedures for collecting, storing, manipulating, retrieving and management of data for the purpose of processing them into information to impact knowledge or otherwise and to support decision making. Oyinloye (2002). Calkins (1977) defined information system as "a chain of operations that takes place from planning the observation to the collection of the data through the storage and analysis of such data and the use of the derived information in a decision making process". An information system is an all important asset if land is to be effectively managed, all information relating to land must be integrated into an information system for it to become relevant to modern day planning and development processes. This is a process of collection, storing, manipulating, analyzing, retrieving, managing and presenting of geographic information in a conceptualized form such that it is relevant in physical development and decision making. It is a decision making tool.

Marble (1987), simply puts geographic information system as an essential tool for handling information in spatial context. GIS has four sub-systems namely: Data input sub- system, data storage and retrieval sub-system, data manipulation and analysis sub-system and information presentation subsystem and these four sub-systems apply evidently to this project. Geographic information technology can be employed in providing planners developers as well as decision makers with the they need to confidently confront a wide variety of threats including natural disasters, crimes, terrorist and similar vices. The college authorities can also employ the use of GIS as a tool in decisions that bother sitting and location of building and structure generally as well as drainage systems to curb and control erosion among many. Geographic information allows geoscientist to apply general principles to specific condition of each location on the earth surface, allows for the tracking of what is happening at a place and helps to explain and provide the understanding on how one place differ from another. GIS is relevant and valuable tool in the information harvest and planning of natural physical, bio-medical, social-cultural, eco-climate economics, engineering sciences and business environments. The global community is now so dependent on computers and computerized information that we cannot do without them, Computerization has opened vast new potential in making decision. The way we communicate, analyze our surroundings and make decision. The power of GIS comes from the ability to relate different information in a spatial context and reach a conclusion about this relationship. Most of the information we have about our world contains a location reference, placing that information at some point on the globe. When parcel or land information is collected it is important to know where the plot is located and its topology. This is done by using a location reference system, such as longitude and latitude and perhaps elevation. Comparing the parcel information with other information such as the location of roads in the vicinity, may show the strategic location of

the parcel of the economic value, this fact may indicate that these roads are likely to assist the easy conveyance of building material to site, and this inference can help us make the most appropriate decision about how busy the road might be during physical development. during physical development.

A GIS therefore, can reveal important new information that leads to better decision making, Different kind of data in map form can be entered into a GIS. A GIS can also convert existing digital information, which may not be in map form into forms it can be recognize and use. For example digital satellite images can be analyzed to produce a map of digital information about land use and land cover. The application of GIS to property and parcel management is fast becoming widespread. In the more developed countries of North America, Australia, and Europe, several municipal countries and local government authorities now use the GIS technology to handle various aspect of land and property (building) management. The World Bank and some other international organization are beginning to spearhead moves towards assisting some less developed countries to implement GIS for land parcel and property management.

In Nigeria, the establishment of Abuja Geographic Information System (AGIS) which has changes the general approach of land. Administration in the City is an eloquent testimony of the usefulness of GIS inland information management. The analogue cadastre was converted to digital format and accordingly, new certificate of occupancy were issued out to former holder of land titles within the capital territory. Prior to the creation of AGIS land transactions in the city was characterized by duplication of titles, delay in searches and land conveyance not properly registered (www.abujagis.com). The effective administration of land and property depends largely on accurate and up-to-date cadastral maps, which can conveniently be created using GIS.

Such maps at appropriate scales are useful in a number of ways including description,

registration and scales of land, generation of revenue, planning, administrative and engineering works Dale(1976). However, some of the common areas of GIS application to land and property management include:

- i. Land/Property taxation
- ii. Assessment of housing quality
- iii. Housing allocation
- iv. Land/Property inventory
- v. Production/updating of land property map
- vi. Districting and master plan
- vii. Reviewing/approving site plans etc.

At this juncture there is need to mention some of the scholars and contributors that have applied GIS in solving cadastral problems in their previous projects and which have yielded good results. This includes:

Akinpelu, (1995): in his own work cadastral information system explained that a relational database management system was used to develop a Land Information system (LIS) for Federal School of Surveying, Oyo, in which full detail of all the cultural (man-made) features on the campus were been represented. The location and topological information for the database was acquired by conventional field survey methods which includes Theodolites (Wild T-16) Traversing, Tacheometry and spirit Levelling (Tilting Level BH-1468). The information gathered consist of three types of features which are point, line and area or surface features obtained after various rigorous mathematical computation processes was carried out, on the obtained data and various corrections applied. The data collected from the field structural techniques such as programming for data processing developed in BASIC language and database

III+ for database structural design. These features were used to represent the real world in LIS applications, in order to provide different types of product results, information" through queries in Base III+ that can aid decision-making.

In similar way, Babatunde, (1998) employed Leica TC600 Total station used for subsidiary traversing, grid leveling and detailing in his data in the field book since the instrument used had no memory for data storage and transfer. The various data sets were processed using applicable mathematical computation processes which yielded the needed information. There was no need for applying corrections to obtained data since the instrument employed had inbuilt programs which corrects for the errors automatically. This information was used to plot the plan showing the various features within the project area. The contouring was done by joining points of equal height together with lines. Since its work centered basically on the data acquisition phase, he does not give explanation on the management of information collected.

Afolabi, (2002), in his own work Geography system provided detailed analysis of features and application of GIS to a more framework of cadastral management for decision making on land investment and development. In its project, spatial and attribute data were acquired through the use of digital equipment (e.g GPS and Total station) and social survey. GIS AJIB and other software were used to link the data in the created database using dBase IV with graphic in AutoCAD Querying and analysis was done through this medium for subsequent information on land.

Yahaya, (2001), in his work Information System his project on the application of Geographic Information System (GIS) in cadastral management, expatiated on the capability of GIS as a tool for managing spatial data for cadastral purposes. He employed a GPS receiver and Total Station (Leica TC600) for geometric and topological data acquisition processes using Landsurveying

method. Attribute data were obtained through social survey. TCTOOLS software was used for downloading data. The graphic representation of the network in both composite and separate layers of the acquired spatial data, and the ability of the created database to be queried using GIS software, IDRISI for windows, ensures the realization of the major objectives of the executed project

Udabor, (2000), claimed that a cadastral information system was created and implemented to monitor and manage land in Olivet Baptist High School, Oyo, Oyo East local Government Area of Oyo State. Here database was created, to meet management needs, which consist of spatial and attribute data. The data sources are from existing topographic map and survey records of the study area. Acquisition of data was carried out through CoGo system. AutoCAD was used for plotting and attribute data was created using ILWIS. ILWIS was also used for linking the spatial data and attribute component to answer queries on land. Queries were used and the results were analyzed for land parcels, land use distribution, areas of parcels less than 12883.387 square meters, fish pond and overlay maps.

Cadastral information system, on the other hand refers to the geographic extent of past, current and future right and interest of private individual and corporate bodies in the land of a country. Such properties are systematically identified by means of some separate designation. The boundaries of the on properties (parcels) and the parcel identifier are normally shown on large-scale maps together with each property, the legal right, the nature use, size and value Akin (2009). Therefore, Cadastral Information System (CIS) had been defined as computerized systems for capture, storage, retrieve, manipulate, analysis and display of land and property related information (Adeoye 1998). It is normally and generally considered to involve a spatially referenced and structured digital database and appropriate application software. These provisions

of the Act leave owners and occupiers of land anywhere in the country vulnerable to the claims of any other individuals who may succeed in getting a statutory or even a customary right of occupancy over the land which was declared to have possessory right under the Act. For such individual, lack of information, cost or fear of bureaucratic hassles likely to be involved have made them unable to avail themselves of the opportunity offered in sections 34(3) and 36(3) to apply to the Governor or Local Government Chairman respectively Certificate of occupancy. Essentially, it is this anomaly in the Land use Act, among other issues that the Land Reform Programme of the president Umaru musah Yar'Adua administration seeks to address.

Geographic information allows geoscientist to apply general principles to specific condition of each location on the earth surface, allows for the tracking of what is happening at a place and helps to explain and provide the understanding on how one place differ from another. GIS is relevant and valuable tool in the information harvest and planning of natural physical, bio-medical, socialcultural, eco-climateeconomics, engineeringsscienceandbusinessenvironments. The global community is now so dependent on computers and computerized information that we cannot do without them, Computerization has opened vast new potential in make decision. The way we communicate, analyze our surroundings and make decision.

Therefore, Cadastral Information System (CIS) had been defined as computerized systems for capture, storage, retrieve, manipulate, analysis and display of land and property related information (Adeoye 1998). It is normally and generally considered to involve a spatially referenced and structured digital database and appropriate application software Furthermore, cadastral information is in various forms which are generally referred to as cadastre. Cadastre was therefore divided to juridical and fiscal. The juridical cadastre refer to legally recognized

record of land tenure as in documents showing the type of right and obligation to landed property properties. The fiscal cadastre refers to cases of taxation and revenue recovering.

The design of geographic database proceeds through several steps. After user's requirement definition, the database structure is created conceptually. The physical design is documented to meet user's requirements. The database is finally constructed and implemented to run a computer. In order to meet the future requirement, expansion capacities must be taken into account. Kufoniyi (1998) further defined the process of structuring as the logical arrangement of data used by a system for data management. Database creation comes after the database has been logically designed. It is the inputting of data into the computer environment of the database for further manipulation in DBMS. Since I have thoroughly examined the opinion of various researchers and scholars on the effectiveness of this project work, the next chapter shall examine the methodology adopted in the execution of the project.

Buragohain (2002) developed a land information system using integrated remote sensing and GIS Technology for Guwahati city, India, in order to come up with an advanced database management system (DBMS) for the city. The methodology adopted in the study was the map of Guwahati city and its surrounding areas were digitized. The industrial data comprised of the characteristics of the draining network, road and railway network as well as infrastructure facilities in the city. Also satellite data are processed and classified using supervised classification method to prepare the land use land cover map. The spatial and temporal changes in growth pattern are recognized from the digital data. At the end, plot-wise urban land use map was map out.

In 1925 Turkey "scadastral system was formed by the state with several legal and organizational modifications. These modifications have resulted in a lack of standardization and inconsistency

in the geometric aspect of the cadastral data, such as the cadastral maps without a co-ordinate system or indifferent coordinate system.

The problem arising from data standardization, data quality, data inconsistency, digital archiving and the slowness in cadastral services forced Turkey to reform its cadastral system to a computer based cadastral information system. In the study, the requirements of a cadastral database were analysed and a spatiotemporal database was designed and developed to fulfill the requirement for spatial, temporal database and spatiotemporal queries for cadastral data. The Spatiotemporal uses Entity-Relationship (STEP) model in combination with the Enhanced Entity Relationship (EER) model.

The result of the Study was a creation of database tables defined in logical schema, where the cadastral and land registry data of the study area were loaded into the database tables created. GIS software was used to retrieve, display, manipulate and analyze the cadastral data. Tella and Rably (2002) was a study that merged the old cadastral records with the new cadastral records, creating a robust cadastral database named VMDS. The VMDS contained both the georeferenced special data and the attribute data. Reghavendran (2002) described how an automated cadastral mapping and land information system could be created. He outlined two main issues of concern for setting up a cadastral information system, i.e., spatial component/survey data parcels in the real world cadastral maps and Non-spatial component describing details such as ownership, tax value etc. He uses spatial database (SDE) for the spatial components and micro station geographic for the non-spatial data. For customized query and reported generation, the database was put in Oracle format. At the end, analysis with the new CIS was unlimited, though it depended on the data that has been put as well as the user requirement.

In his work, "Cadastral Land Information System for Sustainable Land Conveyance in Bauchi state", Shulabu (2008) used the existing analogue map which he converted to digital/.environmentalist, and the economist, Specially in an environment where baseline data is Seam, The lack of adequate functional and coordinated land information system and networks underpins this weak system, requiring that land related agencies maintain up-to-date scientific data, maps, and plans Baba Wuro (2010).

Conclusively, to propagate the switching from analogue system of storing, assessing and retrieving cadastral data, there is need for an urgent application of GIS in cadastral management so as to be able to solve many cadastral related problems in order to build a well-planned, conducive and favorable environment to assist in formulating polices on land use.

CHAPTER THREE

METHODOLOGY

This explains the method and techniques used to achieve the aims and objectives

This work, the execution of this project was based on the following basic principle of surveying

- Working from whole to the part.
- The principle of choosing the method of survey most appropriate to meet the desired result.
- The principle of provision for adequate checks to meet the required accuracy

3.1 OFFICE PLANNING

Office planning which could be termed as office reconnaissance involved knowing the type of instruments, purpose, specification and accuracy required of the survey to be carried out. This led to the choosing of appropriate equipment and method to be employed, also costing of the survey operation was done in the office. Information related to the given project was collected from various sources the coordinate (x, y, and z) of the initial and that of the three chosen controls used for orientation were all obtained from department office.

3.1.1 FIELD RECONNAISSANCE

The project site was visited by all the group members to have the true picture of site for the better planning. The reconnaissance diagram was drawn alongside the carrying out and the reasonable artificial features were fixed along and within the traverse lines, the traverse was fixed to maintain perfect indivisibility.

3.2 INSTRUMENT USED

Selection of instrument to be used is:

- Total station

- Tripod
- Lineartape
- Stealtape
- Fieldbook
- Pencil
- Targetsandtheirtripod
- Reflectorsstandandtarget
- Nails
- Pegs

3.3 MONUMENTATION

In selecting station to represent the perimeter of the while carved, establishment of the station were done so as to define the boundaries of the project study area using a temporary Pegs since the place is Government property, station was established and they were marked with pegs. The peg was firmly even into the ground hence, ensuring that stability of the station pegs in such way that they cannot be temper with.

3.4 TESTS OF DIFFERENTIAL GPS

The two GPS receivers (Tersus Differential GNSS) were tested to ascertain its working capability on two known established points. The reference receiver (base) and rover receiver were setup using the RTK (Real Time Kinematics) mode with boosts from external radio to increase the communication link up and range between the two receivers. The interface was accessed using S1 controller to set the parameter. The data acquired was downloaded using beam methods (Bluetooth) of the windows mobile platform in text format

However, the result displayed the following on the controller:

| | |
|----------------------------------|--------------|
| Status(P): | Fixed |
| Horizontal Root Mean Square (H): | 0.014 |
| Vertical Root Mean Square (V): | 0.021 |
| Satellite Number (S): | 10-4 |
| Communication Mode (Channel): | 4 |
| Time (T) | 11:05:38 |

3.5 CONTROL CHECK

Control check was carried out on the beacons PT 02 and PT 03 in order to ensure whether they were still maintaining their original positions. The reference receiver (base receiver) was set on PT 01 while the rover receiver was set on PT 02 and PT 03 respectively. The following are the results obtained

Table 3.5.1: Coordinate of the observed and the original values of PT02

| PILLAR | NORTHING | EASTING | STATUS | REMARKS |
|--------------|------------|------------|--------|----------|
| PT02 | 935768.084 | 670900.867 | | ORIGINAL |
| PT02 | 935768.099 | 670900.847 | FIXED | OBSERVED |
| DISREPERANCY | 0.015 | 0.020 | | |

Table 3.5.2: Coordinate of the observed and the original values of PT03

| PILLAR | NORTHING(m) | EASTING(m) | STATUS | REMARKS |
|--------------|-------------|------------|--------|----------|
| PT03 | 935791.554 | 670975.362 | | ORIGINAL |
| PT03 | 935791.575 | 670975.384 | FIXED | OBSERVED |
| DISREPERANCY | 0.021 | 0.022 | | |

The result shows that the control pillars were in situ and in good condition for the survey operation. In the case of the instrument, it can be concluded to be in good working condition.

3.6 DATA SOURCE

Control coordinate was given from existing map, which is considered as secondary data. This was plotted using AutoCAD.

3.7 GEOMETRIC DATA ACQUISITION

This involves the acquisition of both northing and easting values of features that are present on the project site. During the data acquisition, Real Time Kinematic method was employed to obtain coordinates of boundary points, as well as details and notable features along the perimeter using total station. Boundary pillars are established and accurately measured. These points serve as reference markers and are essential for maintaining consistency and accuracy throughout the survey. Additionally, these coordinates serve as valuable information for future reference, analysis, or planning purposes. They can also be used to assess potential impacts on the survey area and aid in making informed decisions during the project's development or construction phases.

Data Acquisition

To gather the necessary data for the project, observations and measurements were carried out. Obtaining the information needed to create the project plan was the focus of this stage. The processes listed below were completed.

- i. Selection of control points. Perimeter Traverse
- ii. Detailing

Complete surveying programs with the ability to record data and set parameters are included with the instrument used. Additionally, it uses software modules with built-in memory and has convenient memory management capabilities.

Perimeter Traverse

The act of traversing is the survey of a group of interconnected lines, known as traverse legs, the ends of which have been marked in the field and the lengths and directions of which have been established by observation. Traverse stations are places of change of turning. Open and Closed Traverses are the two basic categories into which traversing can be placed.

Closed traverse always begins and ends on sets of known points (points with known coordinates previously established). Perimeters are frequently encircled by shapes, such as polygons, in closed traverse surveying. Although this type is expected to be employed in all projects in surveying generally.

An open traverse consists of a collection of traverse lines that are connected but do not begin and end at a known point. When no controls are present where the traverse is to stop, this type is typically utilized. In this kind of traverse, the observer's main responsibility is to make sure that the task is being checked at each stage. Surveys of this kind are frequently used in the engineering industry, such as route surveys.

The closed traverse type was employed in this project as it was started on an existing control point (PT 02) and closed on the same control (PT 02).

Base Station Setup

The base station is required in order to ensure an accurate position to be used in the topographic survey of Extension to Textile Factory. The use of a base station is now a standard routine in surveying practice; this is to validate the fundamental principle of carrying out a survey “**from whole to part**”. This means that networks of horizontal and vertical control points are first established. The temporary adjustment (centering and leveling) was performed on it. All the connections necessary for RTK mode stated below were carried out,

1. The base station comprising of Tersus GNSS GPS receiver shown in figure 3.1 below was set up on a tripod stand on PT 02.

Figure 3.1 Tersus GNSS GPS receiver

NB: The position of the base station used is 935768.084mN, 670900.867mE. It was located in an area free from obstruction and interferences. It has been set to the WGS 84 system with Clarke 1880 ellipsoid.

The procedure for the data capturing is stated below;

- i. The instrument was switched on using the power button and also the data logger (**TC20**).
- ii. Then the instrument was placed on the tribrach which was already attached to the tripod and levelled.
- iii. On the data logger, the **Nuwaapp**, Survey Office software was launched.
- iv. The software was allowed to load and then, on the Project creation page, a project folder called '**CIS**' was created and then opened.
- v. On the series of pages that followed however, the datum was selected as 'Minna', the mask angle as '15°', while the minimum observation time was set at '5 minute'. After this page, the Base page was loaded.
- vi. On the instrument **Connect page** (the Bluetooth connection page), the base station instrument serial number 52000754 was selected and down the page, the 'connect' button was clicked. This connects the logger to the base instrument.

- vii. On the Base page, the **get location** icon was clicked, and this brought the approximate coordinate of PT 2 control, the coordinate was then corrected to the values obtained after this, the 'start' button was clicked and the base observation commenced.
- viii. The Rover instrument's battery was then fixed into it and switched on using the power button then mounted on the tracking rod (a single legged pole) and tightened.
- x. The tracking rod was set at 2.00 m as height of the instrument.
- xi. On the instrument **Connect page** (the Bluetooth connection page), the base station instrument serial number 52000754 was then disconnected and the Rover instrument serial number 52000764 was selected and down the page, the 'connect' button was clicked. This connected the logger to the Rover instrument. The voice information **FIXED** was then heard from the instrument.
- A complete setup of the base and the interface of the Project Creation page are shown

Figure 3.2 Showing the project creation page on Nuwa app

FIELD OBSERVATION

1. After setting up the base, the rover instrument with serial number 52000764 was taken to site.
2. **NOTE:-** Each station in a differential GPS observation is typically observed independently (though with direct reference to the base station), i.e., the instrument is placed on each station one at a time until the final point or detail in the site is observed.
3. The instrument was placed on the first station i.e. the base of the tracking rod was placed on the center of the pillar.
4. On the data logger, the Nuwa app was launched and the Survey page of the app was clicked. On the Survey page, the **get location** icon was clicked to obtain the Northing and Easting of the station.

5. **NB:** Given that the time segment of the instrument has been set to 5secs already, the observation automatically ends when its period of the time segment already pre-set elapsed
- iii. The StationID was then changed from P1 to P2.
6. After 5secs of observation, the observation stopped automatically and then the instrument was moved to the next station i.e. P2
7. NOTE:- that the data logger was not switched off after the first station had been observed since the stations are not far from one another i.e. not more than 50m from each another.
8. On the data logger with the Survey page on, the 'get location' icon was clicked and the observation started since the instrument had automatically given the next station name. The observation was allowed for 5sec again.
9. The process in step (v) was repeated for all the subsequent stations and other details that were observed on the site.
10. At the end of the observation, the instrument was switched off. The Survey page on the data logger was closed and the data logger was also switched off (though in the warm boot mode).
11. The data logger was taken to the base station and switched on again. The instrument's serial number was selected on the Bluetooth page which also led to the Base station page.
12. On the base station page, the 'stop base' button was clicked and then the instrument was
13. switched off including the data logger.

3.7.1 ATTRIBUTE/SOCIAL SURVEY

This aspect of data acquisition entails the collection of other data which geometric in nature. Such data were directly related to the features to which geometric data was acquired. They included building names, the purpose of which the building is used for. etc.

To collect attributed data, survey was employed. This involves oral interviews, reading information from sign posts, wall signs, virtual observation, etc.

3.8 DATABASE CREATION/IMPLEMENT

For efficient and effective management of data in the computer environment, data items are usually arranged and stored in a database or databank. The content of this database could be in form of a text, number, polygon or graphics. The creation of this database involved the combination and storage of the acquired graphical and attributes data obtained in former designed GIS database of a generic structure for the purpose in spatial analysis and queries on project site

In the creation of a land information system data mode, a widely used technique called layering was employed. The features that are present within the project site have been classified into different layers in the AutoCAD software independently. The polyline entities were joined using the polyline tool while appropriate symbols were used for the point entities. These layers were then exported to ArcGIS environment where shape files were created using attributes fields as conceptualized in the schema. These attribute table were then populated accordingly with attributes values for each particular entity as observed in the field and from the social survey template (attached as appendix)

The personal Geodatabase was then created finally in Arc Catalog environment. Where other tables that are non-geometric were created while the already created shape files were imported. Relationship between these tables were also established and the tables were later populated in the Arc Map environment. The following are some of the tables created

3.8.1. DATABASEMANAGEMENTSYSTEM(DBMS)

According to Dale and McLaughlin(1998), database management system was defined as a computer program to control the storage, retrieval and modification of data in the database. DBMS comprises of set of programmers which are used to maintain and manipulate the data orderly and acts as the central control over all the interactions. It manages that data using alphanumeric data with limited capabilities of performing spatial queries

A DBMS must allow the definition of data and their attributes and relationships as well as providing security and on interface between the end users and their application and the data themselves it reduces redundancy. Therefore, Arc GIS 10.2 version was used to create, manipulate, maintain and access the database easily.

3.8.2. DATAQUALITY

Some forms of quality control and quality assurance were incorporated in the project at every phase. These include conformity with data templates, data competences and data accuracy. Conformity with data templates in this premises refers to the degree to which the captured data conformed with the designed templates, while data competence was understood as the degree to which the available data in the report and for which there are specific templates have been extracted.

3.8.3 DATAINTEGRITY

The data captured as exactly downloaded into the system then exported to AutoCAD via notepad and eventually into Arc GIS. The process involves ensuring that the data in the database were accurate and setting of certain constraint to prevent inconsistency in the database.

3.8.4 DATA SECURITY

Security is of great concern to land administration because of the legal implication of cadastral records. Security of the records is of almost importance to all concerned. These includes:

- Physical system security
- Physical security: The use of burgling proof, fire-fighting equipment-controlled access, proper records of the moment of personal and our of the office circuit break
- System Security: Uninterrupted power supply (UPS) will be used to control voltage, use of passwords and backups

In view of the foregoing, locking mechanism was adopted to protect the data in the database from unconscious deletion. Password was used to prevent unauthorized user from breaking into the database and a backup was created for the whole project on the rentable DVD.

Having succeeded in analysis the methodology employed in the execution of this project to arrive at the successful completion. it is equally necessary to examine the processes undertaken to ascertain the reliability and effectiveness of the created land information system

CHAPTER FOUR

4.0 DATA PROCESSING AND PRESENTATION

4.1 SPATIAL ANALYSIS

Spatial analysis is a specialized function that distinguishes GIS from other information systems. It entails the examination of spatial and attributes characteristics of geographic features that are within the database to establish relationships from which spatial problems can be tackled. In this project work, spatial analyses were performed to select, combine and intersect existing geospatial data-sets in order to generate new information suitable for answering specific spatially-related questions.

The results from these analyses can be shown in a number of ways depending on the required output format. Where attribute information about map features is required, they can be presented as tables containing such values as are needed from the query analysis. They can also be presented as maps with legend information showing the queried features and their topological relationships with other features shown on the map.

For this project AutoCAD 2007 was used to carry out the plotting of all the parcels. The drawing was exported to ArcGIS 10.3 where all other operations were carried out.

4.2 Spatial Query

Searching of data components using certain criteria of retrieving them from the database is known as spatial query. The information retrieved is used to support decision making. The Cadastral Information System (CIS) plays its role when a relational database is linked to graphics in real time.

A good Cadastral Information System (CIS) allows the user to select records or attributes in the database and to view the result on coverage displayed which can be printed on a hardcopy.

4.3 Query Design

A query design is a precise definition of what is to be selected from the database. For example, the following queries designs were used in this project:

- | | |
|--|----------------|
| 1. | Query by P |
| Status=Developed, Puse=commercial | |
| 2. | Query by Puse= |
| Residential | |
| 3. | Query by Puse= |
| Residential, Parea=1345.624sqm and Ownersname=Mr Qudus | |

4.4 Testing Of Database

This is the test carried out to determine whether the relationship between the geometric data about the objects and their attributes is capable of being retrieved. This was done by designing a simple query and running the query to see if the desired result is achieved. The query ran, hence the database was confirmed fit for analysis.

4.5 ExistingParcelsandBlocks

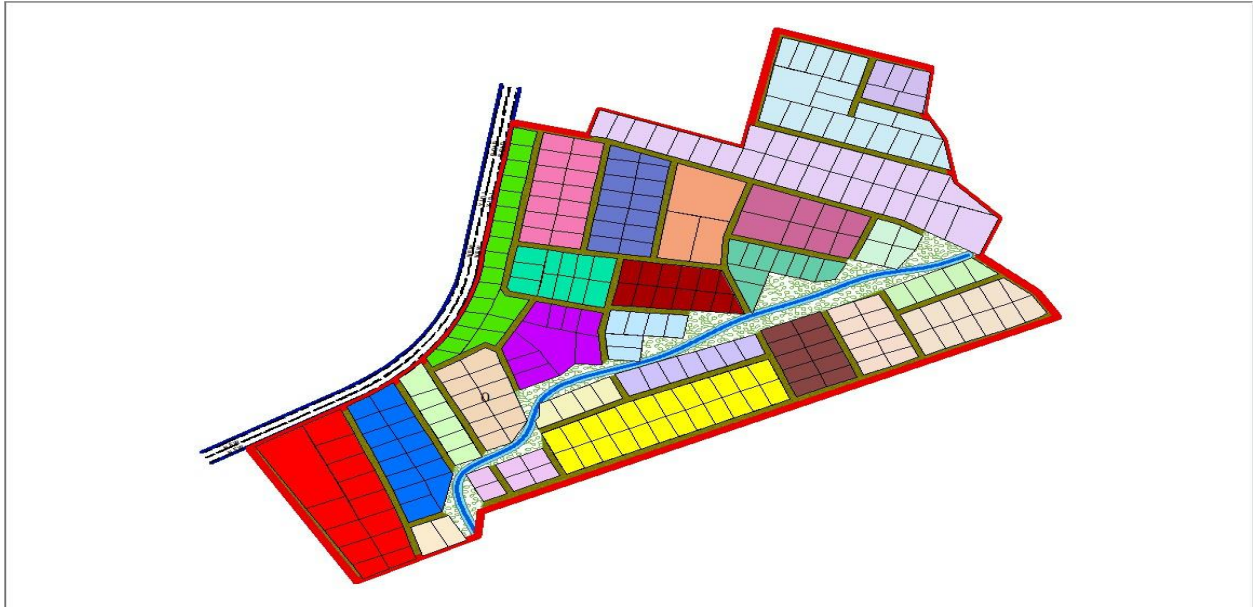

Fig4.5.1:-theexported cadastralplan ofthestudyarea showingtheblockswithinthearea

Fig 4.5.2:- the exported cadastral plan of the study area showing the all the parcels within the area.

Fig4.5.3:-thecadastralplan ofthestudy area showing theboundary,

4.6 SpatialQuery

Queries were designed for the purpose of retrieving information from the database. The queries performed in this project gave answers to certain generic questions asked from the database. This was made possible as a result of the implicit link of both the spatial and attributes data. The queries were based on the products from the analysis carried out on the database.

4.6.1 SingleCriterionQuery

A single criterion is carried out where one condition is used to design query. This condition is used to retrieve the information from the database.

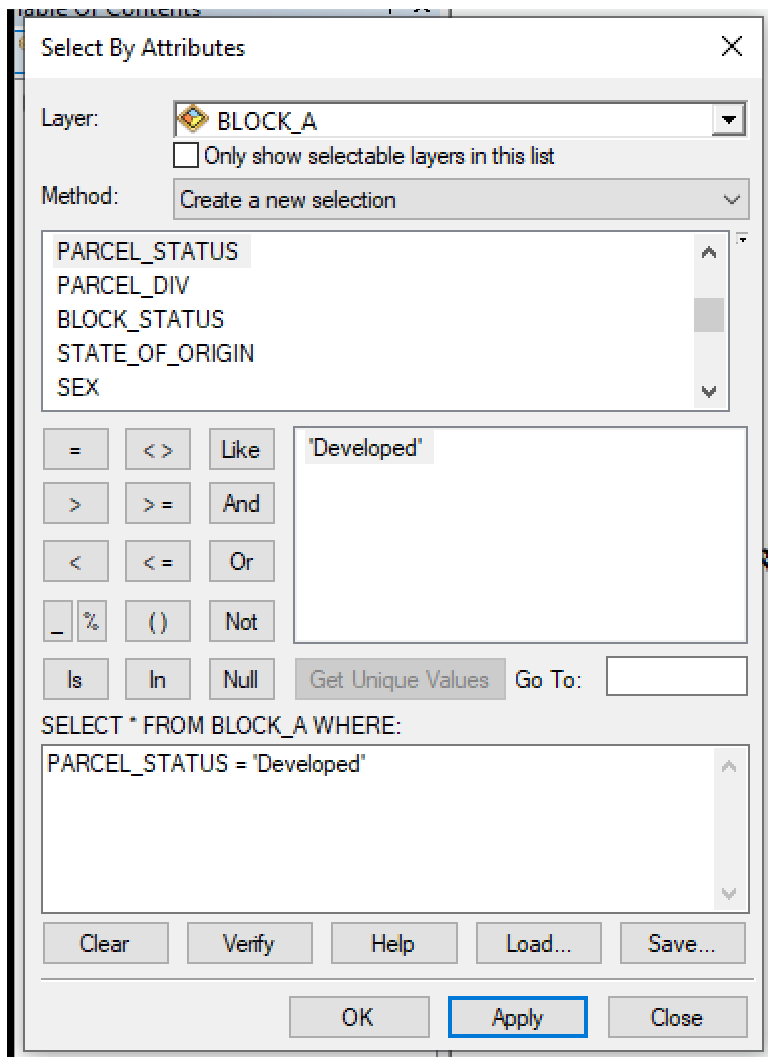

Fig4.6.1.1:-QueryforParcelstatusfordevelopedPurposesintheStudyArea SYNTAX;
 ([Parcel_status]) ='developed')

4.6.2 QuerybyParcelStatus(Developed)

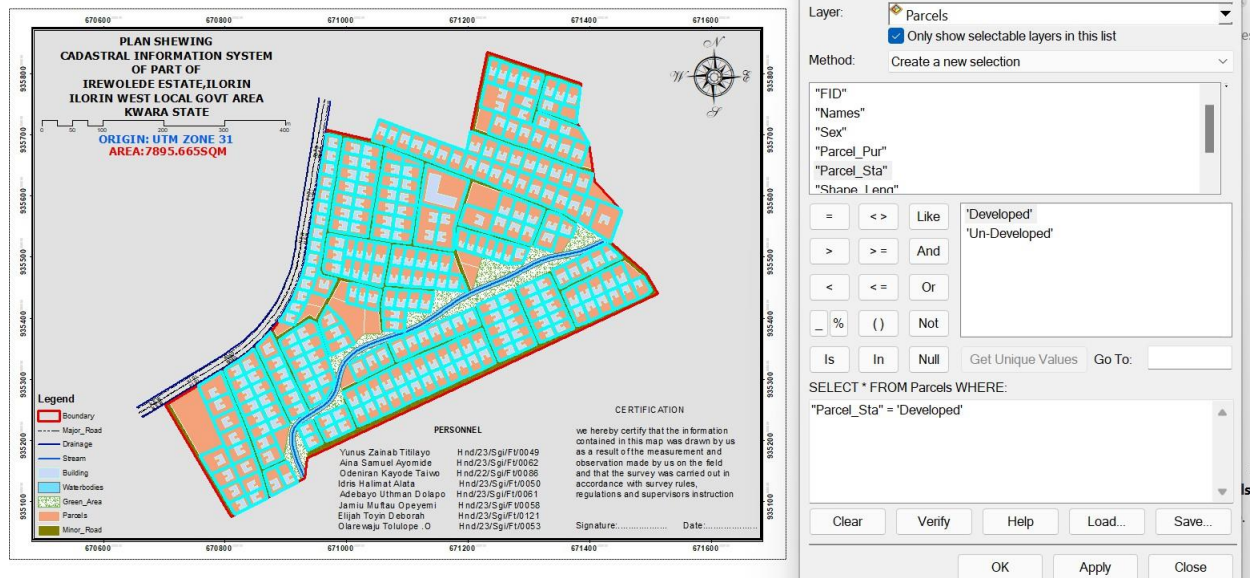

Fig4.6.2.1:ResultofQueryforParcelUsedforResidentialareainblockAinthestudy area

SYNTAX;([Parcel_status])='developed')

4.6.3 DiscussionofResult

Figure 4.6.2.1 Shows parcels that are meant for developed purposes. It consists of the syntax model or the query builder box, attribute table as well as the map of the selected plot in light green color. The result shows that 8 parcels out of the 20 parcels are meant for commercial purposes.

4.6.4 Query by ParcelStatus(commercial)

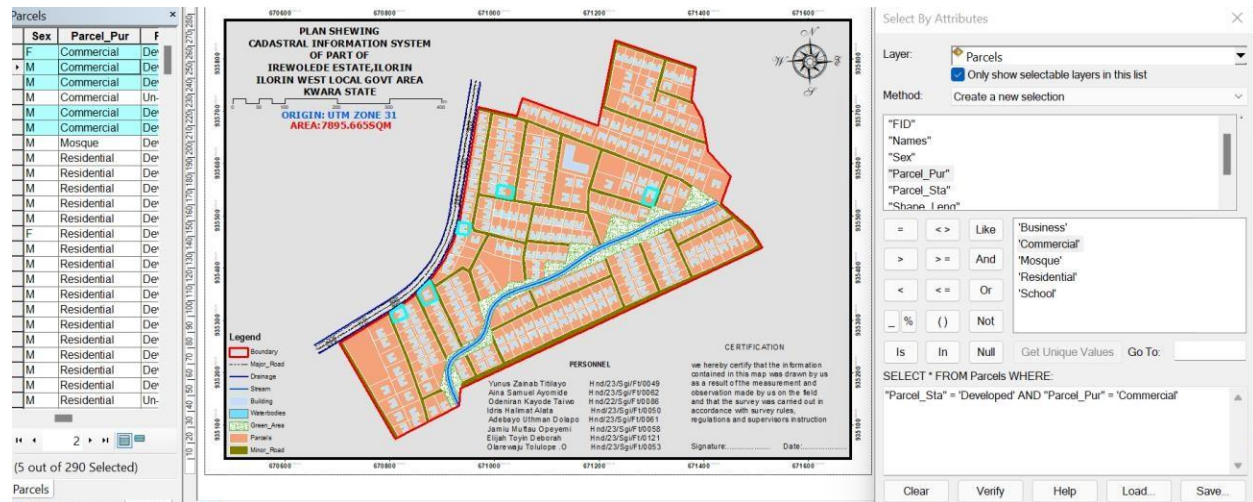

Fig4.6.4.1:ResultofQueryforParcelsthatarecommercialpurposeinthestudyarea. SYNTAX; ([Parcel status]) ='commercial')

4.7 DiscussionofResult

Figure 4.6.4.1 shows parcelsthatalreadyhavesometypeofcommercial onit.It consists of the syntax model or the query builder box, attribute table as well as the map of the selectedplot inlight greencolor. Theresult showsthat 5parcelsoutofthe290parcels have been developed.This information, however will help in informing the necessaryquarters the levelof development within the layout.

4.8 MultipleCriteriaQuery

The database created is then used for implementing several selection queries in determinationofuser-definedrequirementssuchasparcelswhoseoccupiersareactualowners,

occupier's citizenship, occupier's occupation, number of residents in each flat, selection of unoccupied flats and other such security.

4.8.1 Query By Parcel Use And Parcel Status (Parcels meant for school, residential, commercial purposes that are “Developed”)

Query was carried out in two stages, parcels meant for residential purposes were first queried by means of the parcel use field. In this case parcel use was selection criteria. The shape file data of the query was exported as a layer and named accordingly. Next, the attribute table of the query result was queried by means of parcels meant for residential purposes that are yet to be developed i.e. Developed Parcels using the “Developed” selection criteria. This gives result for the parcels meant for residential purposes that are developed this also will help inform on the level of development within the layout.

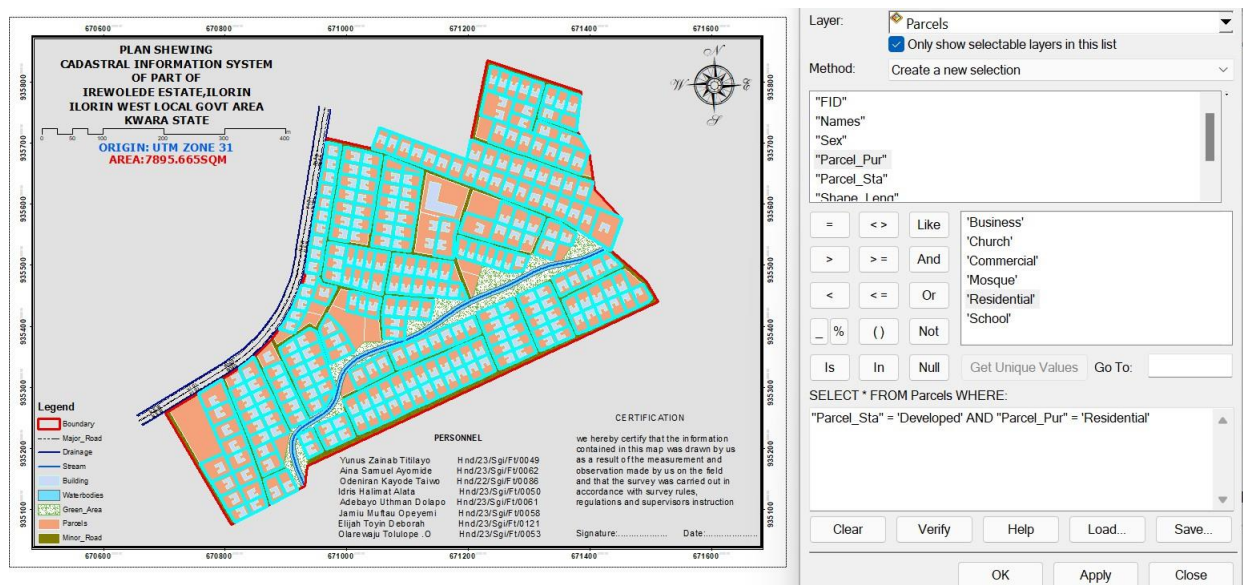

Fig4.8.1.1: Screenprint showing parcel use and parcel status in the layout.

SYNTAX;PARCEL_USE='Residential'ANDPARCEL_STATUS='Developed'

Discussion of Result

Figure 4.8.1.1 shows the syntax modeled, the attribute table and the map of the multiple criteria queries ran on parcel meant for residential purposes and number of Developed residential purpose parcels within the study area, they are highlighted in Light green color. The result showed that 265 of the 290 parcels are developed.

4.8.2 Query By Parcel Use (Commercial) And Parcel Status (Parcels meant for commercial purposes that are “Developed”)

Following the procedure in the query for parcels meant for residential purposes that are yet to be developed. All parcels meant for commercial purposes were first queried and then, the resulting attribute table, query was carried out for parcel for which are Developed.

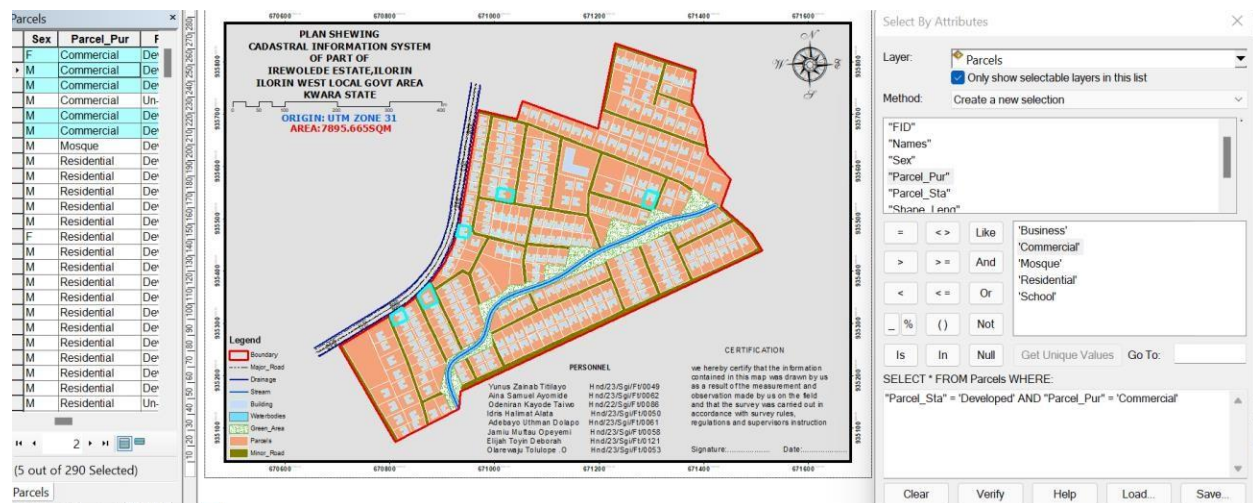

Fig4..8.2.1: Screenprints showing parcel meant for commercial purposes that are Developed in the layout.

SYNTAX;PARCEL_USE='Commercial'ANDPARCEL_STATUS='Developed'4.7.2.1

Discussion of Result

Fig 4.8.2.1 shows the result of syntax modeled, attribute table as well as unformatted map of developed parcels meant for commercial purposes. The table shows that all the 5 parcels meant for commercial purposes are developed. This is a pointer to the high rate of commercial developments in the study area.

4.8.3 QueryBy10mProximity tothestream(Parcelwithin 10mproximitytothestream).

Following the procedure in the query for parcels within close proximity to the stream (10m), query was carried out to show the parcels within close range to the stream.

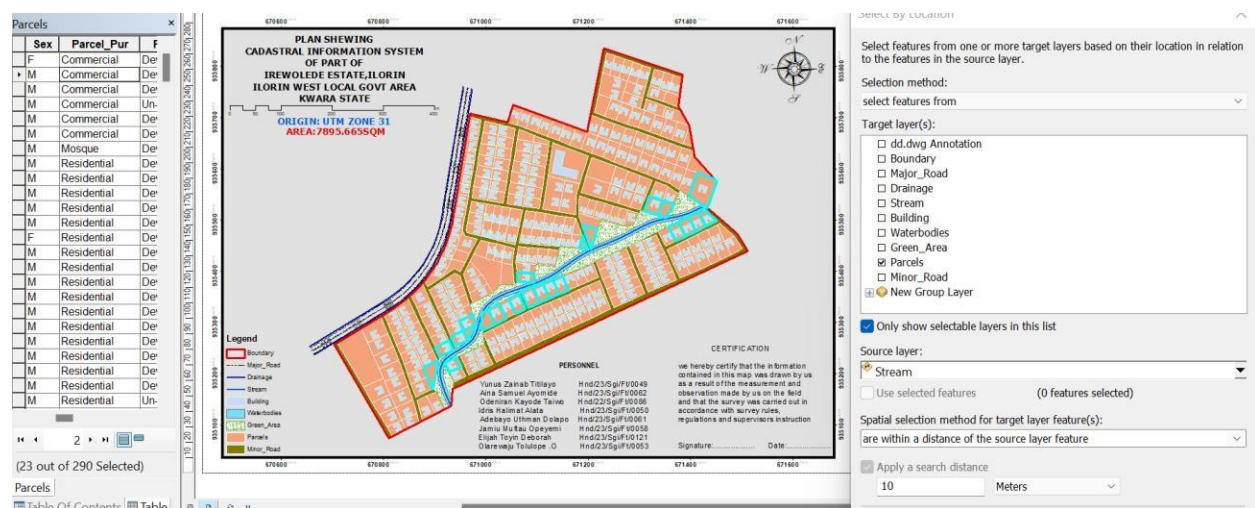

Fig4.8.3.1:Screenprint showing parcel within 10m proximity to the stream

4.8.3.2 DiscussionOfResult

Figure 4.8.3.1 shows the result of `syntax modeled, attributetable`. The table shows that only two out of all the parcels, only 25 parcels are within 10m proximity to the stream.

Fig4.8.5.4Screen-shotshowingthedatabasecreated forthestudy area

CHAPTER FIVE

SUMMARY, CONCLUSION AND RECOMMENDATIONS

5.1 SUMMARY

This project refers to a computer based record keeping storage, management and retrieval systems for land and property records attempts to demonstrate the one with which land data can be converted into a powerful information system is recognized the acquisition and effective use of information is fundamental to the survival of any organization hence attempts were made to show how geographic information system can be used to solve problems associated with cadastral management. Total station set 450 was used to acquire geometric data and attribute data was acquired through social surveys. Database was created from the acquired data in order to make retrieval, manipulation and data update relatively easy. Analysis of result was done using relational database model (Tables); and structured query Languages (SQL) in ArcGIS 13. The Queries invoked in the database, generated information that could be used in decision making and physical planning of the study area in the future. The results are presented in both soft copy and hard copy. The process of data acquisition, data processing and information presentation, accumulated in the writing of a comprehensive report

5.2 PROBLEMS ENCOUNTERED

The following problems were encountered in the course of the project,

1. Method of data acquisition. Acquiring cadastral data using land surveying method posed a lot of challenges. Some of the parcels were fenced and access denied. Hence only buildings which could be measured were included. This implies that the data acquired were less than what were actually available in the site. Remote Sensing method Using high resolution satellite imagery

though expensive for small scale project like this would be the best method of data acquisition since it overcomes all these challenges.

2. Lack of cooperation of some of the parcel owners. It was difficult to obtain non-patial data from parcel owners. The structured interview did not yield the most expected results as some of them were not around because they were not informed while some respond to us reluctantly and not too sure of their answer to our questions. Unavailability of information about the estate. The Kwara State Department of Lands and Housing could not provide any data about the Estate. If the master plan of the Estate were available, it would become a guide to check violations in the estate. Availability of the socio-economic and demographic data would aid in the spatial analysis of service area.
3. During the execution of this project incessant power failure causes delay in the processing and manipulation of the acquired data which extended the time used for processing and report writing of the project.

5.3 CONCLUSION

Land is a natural resource and its potentials may be harnessed effectively where there is proper documentation of title and constant updating of records pertaining to ownership and transfers. The project has succeeded in demonstrating the usefulness of GIS in cadastral management of Irewolede Estate Area as it is essential for the development of any community. The database created will definitely aid efficient planning, sustainable physical development, easy retrieval and updating of land related information of the study area. The basic cadastral queries invoked, showed that a cadastral database should store historical information on land parcels and related objects.

The technologies available will not only allow integrate the various spatial and non- spatial datasets, but will enable online gathering, recording, warehousing rtheving, disseminating and employing the data, which will lead to improve the effectiveness and efficiency of land management both from the perspective of the comminn man as well as that of decision makers implementing land based development activities at grass root level.

Having been part of the field work, data processing, analysis and information presentation, it is expedient to conclude that the aims and objectives of this project have been achieved. Hence this cadastral database has the capacity to provide current and near sufficient data within reach for the implementation of large scale or multipurpose cadastral information system in Kwara State with possible potential of being transferred to other States in Nigeria.

5.4 RECOMMENDATIONS

Havingexecutedthisprojectsuccessfully,thefollowingrecommendationsaresuggested:

- i. It imperative for the authorities to set in motion machinery that would encourage thecreation of a database for all the properties and ensure the proper management of the information derived from time to time, in this way, a comprehensive land informationsystem could be established.
- ii. There is need to unifyall fragmented cadastraldigitaldatabase executed allover the country to form a larger pool. This would reduce man hour and time lostto accessing file of cadastral plan/maps
- iii. There isneed fortheFederalGovernment, stategovernment andLocalGovernmentsto keep land occupants informed about changing land policies.

- iv. Kwara West Local Government should use the product in aiding their Town planning department, internal revenue board to mention a few, in the discharge of their constituted duties.
- v. Efficient planning for provision of utilities (like electricity, sewage and water) to meet the needs of the residents and monitoring of illegal structures.
- vi. Providing complete and up to date information for prospective investors and stakeholders in the housing sector.
- vii. This implementation of this system should be encouraged at the lowest tier of governance as this would help reduce execution time and costs in situations where similar system is to be executed all over the country. This would also aid in the overall integration of spatial databases in the country.
- viii. The project products, stages and the lessons learned should be presented to relevant departments, establishments or institution that may be willing to implement similar system in the future as part of their corporate service responsibility to their host community.
- ix. Aspect of GIS development since land management requires that sound management to be performed with Surveyors should be encouraged to extend their operations to include some the support of an effective decision support system.

**COSTING OF THE CADASTRAL INFORMATION SYSTEM (PROJECT) OF PART OF
IREWOLEDE ESTATE, ILORIN**

RECONNAISSANCE

| S/NO | PERSONEL OFFICER | DAYS | UNIT RATE | AMOUNT |
|------|--------------------|------|-----------|-----------|
| 1 | Senior Surveyor | 6 | 98,800 | 592,800 |
| 2 | Assistant Surveyor | 6 | 58,000 | 340,000 |
| 3 | Chain Mem | 6 | 30,000 | 180,000 |
| 4 | Transportation | 6 | 40,000 | 240,000 |
| 5 | Basic Equipment | 6 | 65,000 | 270,000 |
| | Total | | | 1,622,800 |

TRAVERSING

| S/NO | PERSONNEL OFFICER | DAY(S) | UNIT RATE | AMOUNT |
|------|--------------------|--------|-----------|---------|
